- **Optical Music Recognition (OMR)** enables **preservation** and **accessibility** of historical manuscripts.
- Neural network-based methods require a **large amount of labeled data**, which must be obtained at a high cost.
- This paper focuses on detecting bounding boxes of staves, a common step in OMR so-called **Layout Analysis (LA)**.
- The main goal is to train a LA method using scarce labeled training sets.

FSAE: Few-shot Selectional Auto-Encoder

Our proposal (FSAE) is based on the adaptation of an existing approach (Selectional Auto-Encoder) to work with partial annotations for LA. It consists in several steps:

1. Manually **annotating** bounding boxes.
2. Adaptation of **image scale** according to the half of a window height ($\sigma = 0.5$).
3. **Extracting** λ random patch samples around the annotation, as many as needed (*oversampling*).
4. **Training** the model that includes a masking layer to ignore non-annotated pixels while training.

Fig. 6: Examples of retrieved staves by using λ training staves.

Conclusions

- We introduced a novel layout analysis framework for OMR working under few-shot conditions.
- Our approach, FSAE, enables partial manual annotations to train a robust staff-retrieval model.
- Annotating between 8 and 32 staves is sufficient to obtain competitive performances.
